

## Phone and Linux desktop at the same time

**Egg, 15 June 2020:** *AVMultimedia has got “new blood”. With AVMultiPhone, a new version of the AVMultimedia distribution is now available, which is a smartphone and Linux desktop at the same time. Why this makes a lot of sense and how it came about is what this blog is about.*

### AVMultiPhone: The first “real” Linux smartphone

A few months ago it was reported here how [Android smartphones can be equipped as “free” as possible \(i.e. with open source\)](#). This process is anything but simple. More importantly, however, the Android ecosystem (analogous to the apple cosmos) is generally not open so that smartphones can be populated according to one’s own requirements.

More than ten years ago, the [Nokia N900 came on the market as a Linux phone \(see here\)](#), but it was not really free. A considerable part of the software was kept under lock and key by Nokia.

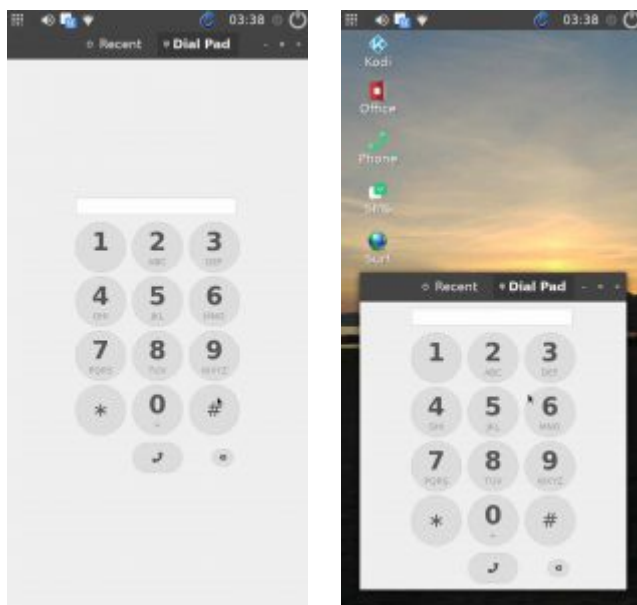

The N900 was technically far superior to all other smartphones at that time. Unfortunately, the N900 came a few years too late, especially the Apple company was much happier with offering the apps than Nokia did. In 2011/12 Nokia was taken over by Microsoft. The N900 was mature, but Microsoft did not want to market a Linux device.

After that, it was quiet around native Linux smartphones for almost a decade. There were devices like [OpenMonko](#), but the key data were so “weak” that it never really got past the design phase.

In the meantime, Android was able to start its triumphal march unhindered. Although a Linux kernel works in the substructure, Android is so interlocked with the other services

of the search giant that there can be no talk of an open smartphone.

Between 2011 and 2017 there was an attempt by Ubuntu to port Linux with **UbuntuTouch** to the smartphone, but the project was abandoned or handed over to the community in 2017 without more than one two niche devices. At the end of 2017 another attempt was started with the **Librem5 from Purism**, which is still in progress today.

And yet there is a chance that the market could change in 2020. The **PinePhone**, announced in 2019 and first delivered in early 2020, is a smartphone that can be freely equipped with Linux. However, probably more important for the success of PinePhone is that the smartphone is inexpensive at around 150 Swiss francs (149 USD).

Currently, the PinePhone comes with **UBPorts (the open successor of UbuntuTouch)**. UBPorts is quite mature and has a surprisingly large app store. However, “normal mortals” cannot upgrade common Linux programs under UBPorts.

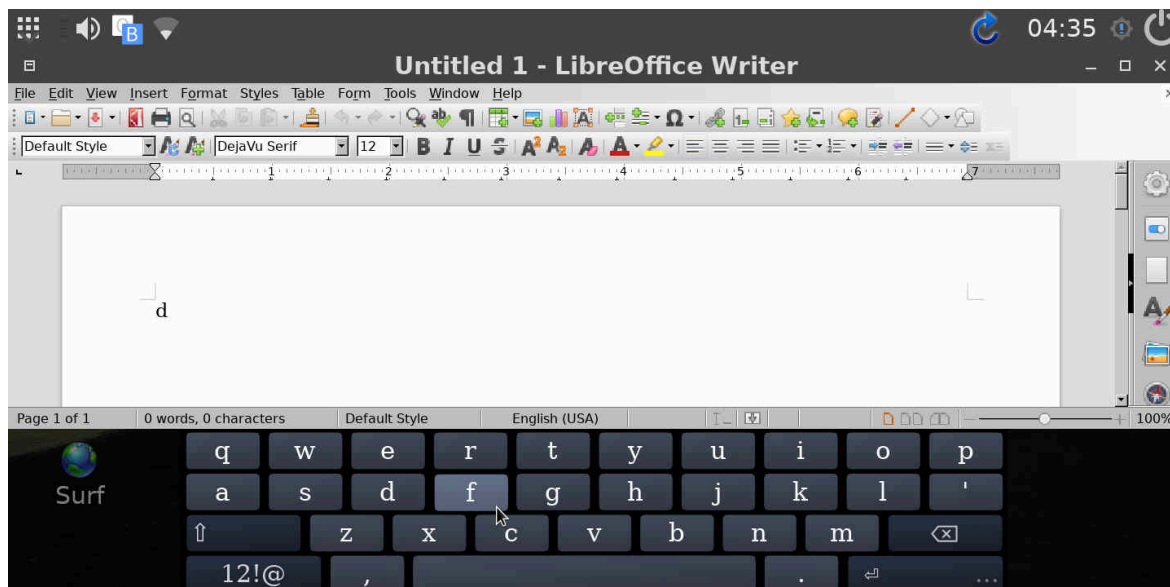

Besides there are several attempts to ship the software of the Librem with a different Linux substructure, the best known variants are **Mobian Phosh** and **PostmarketOS Phosh**. As much as the “Phosh” representatives have a normal Linux substructure, it is not possible to work with desktop software on it. This is due to the fact, that Phosh uses a 1:2 screen management.

This has the advantage that icons and font size are well readable, but at a resolution of 720 x 360 pixels, most Linux programs do not run. But the PinePhone has a resolution of 1440x720 pixels.

For current smartphones this may seem “meager”, but first of all the PinePhone costs only about 150 francs and secondly a resolution of 1440x720 pixels is quite sufficient to equip the PinePhone with a classic Linux desktop.

And this is exactly where AVMultiPhone comes in. AVMultiPhone is not about emulating

all the features of the current smartphones with Linux. AVMultiPhone rather offers a Linux desktop on the smartphone, with which of course and of course also phone calls can be made and SMS can be sent. And that is why AVMultiPhone is the first real Linux smartphone.

## 10 Reasons to use the Linux desktop on your smartphone

- Firstly, I am completely self-sufficient with a Linux smartphone. I can perform all desktop tasks directly on the device.
- Secondly, I don't need a cloud for this, the data remains on the device and I can always drag a copy to a second data carrier.
- Thirdly, I can always change the SD card on the road, yes AVMultiPhone currently runs directly from SD card.
- Fourth, I can mirror the desktop to a larger screen via USB and/or WLAN at any time.
- Fifthly, I have (almost) all Linux programs at my disposal, which I can use at any time without the need to register.
- Sixth, I no longer have to copy data back and forth between my smartphone and desktop, because I have everything available on one device.
- Seventh, it's just cool to be able to make normal phone calls or receive or send text messages on a normal Linux desktop.
- Eighth, AVMultiPhone is suitable for all ages. Parents appreciate a device that does not collect data, kids do not end up in app addiction and older people get a device that is very easy to use.
- Ninth, AVMultiPhone is open source and can be used and extended freely.

- Tenth, AVMultiPhone is very slim. With about 1 GByte of software, all common desktop applications are included: LibreOffice, GIMP, Inkscape, Paint, Kodi as well as VLC/MPV (media player), just to name the most important programs.

## AVMultiPhone is portable and slim like rank

AVMultiPhone is based on **PostmarketOS**, which in turn is based on **Alpine Linux**. Alpine Linux works with BusyBox and Musl. “Normal mortals” should only understand “station” when using these terms. At this point it should be said that programs under Alpine Linux need much less memory, because the used libraries (BusyBox as well as Musl) use resources more economically.

For comparison: AVMultiPhone needs about 1 GByte (including all desktop applications). Mobian reaches this size with the basic system alone. The difference in speed between AVMultiPhone and Mobian is noticeable. Although Mobian uses a SD card that is three to four times faster, starting LibreOffice takes well over 20 seconds, AVMultiPhone takes about 6 seconds.

Because AVMultiPhone is based on PostmarketOS, AVMultiPhone can be ported to currently more than 200 devices. Mobian currently runs exactly on the PinePhone. A look at **LinageOS** and **System /e/** shows that both free Android representatives do not even support half the number of devices.

## Ten steps to start with the AVMultiPhone

To work with AVMultiPhone, the following points are currently recommended.

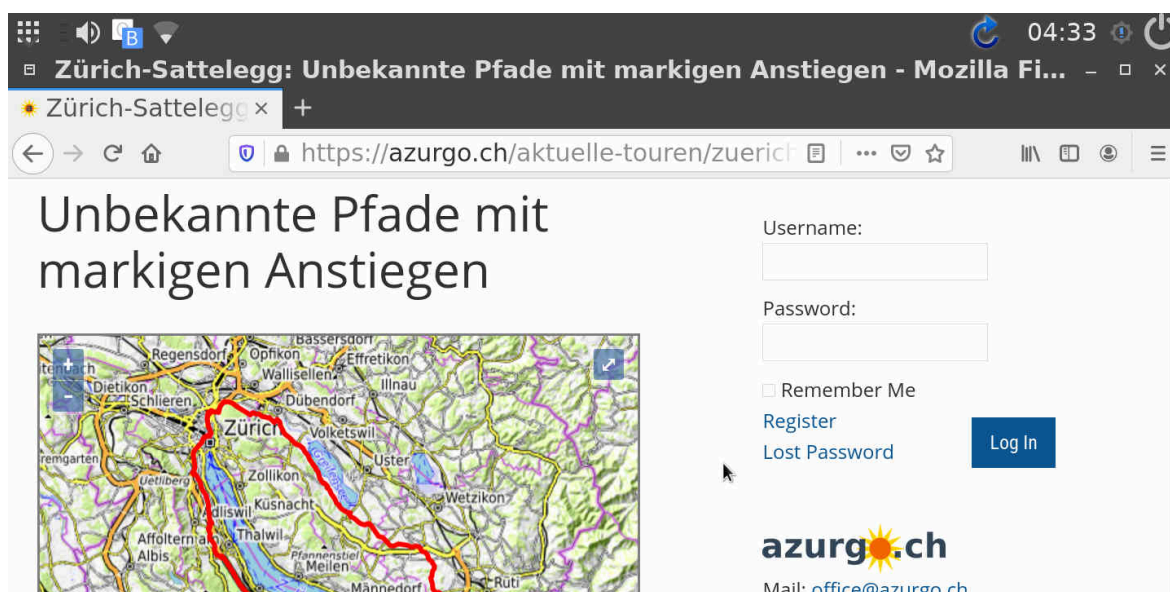

- Get the file from [sourceforge.net](https://sourceforge.net) or [osdn.net](https://osdn.net). The file can be found in the PinePhone folder (current name postav\_200616final.img.gz).
- Open the Linux console and enter the following command: `gunzip -c | dd`

of=/dev/sdx bs=64M (sdx must be replaced by the letter of the SD card).

- Insert the SD card with the PinePhone switched off and start the device
- The default password for the user 'archivista' must be entered in the start screen. Currently this is: 1234 (root password also: 1234).
- After logging in, the SIM password is requested (if a card is inserted).
- The screen is rotated between portrait and landscape format by clicking on the blue icon in the upper right corner.
- All programs can be found in the menu icon on the far left.
- WiFi and other network connections are set up via the fourth icon of Links (Network Manager).
- The volume of the tone can be controlled directly via the phone's keys.
- A click on the off button will log you off (after that you can log back on by clicking the button again).

## AVMultiPhone: Conclusion and outlook

AVMultiPhone offers on the PinePhone a full Linux desktop with integrated telephone. AVMultiPhone was created because there is no Linux desktop on the smartphone yet. The development on the PinePhone is not finished (this applies to all PinePhone distributions). Currently not so great is that there is no support for the camera. It can be expected that this functionality will be available in the near future (first users describe successful activation).

The basic version is currently delivered in English. Other languages can be retrofitted. To do this, use the package management of Alpine Linux. Start the console and search

for packages with 'apk search xyz' and install the desired software with 'apk add xyz'.

The speed and extent of AVMultiPhone development depends on the interest of the users. Inquiries for special implementations will be implemented with pleasure (if possible, primarily time).

In conclusion, AVMultiPhone shows impressively how little effort can be put into open source to achieve more than just good results. Or, to put it another way, how something can be created in a week that previously had to wait ten years.
